CS 435: Algorithms

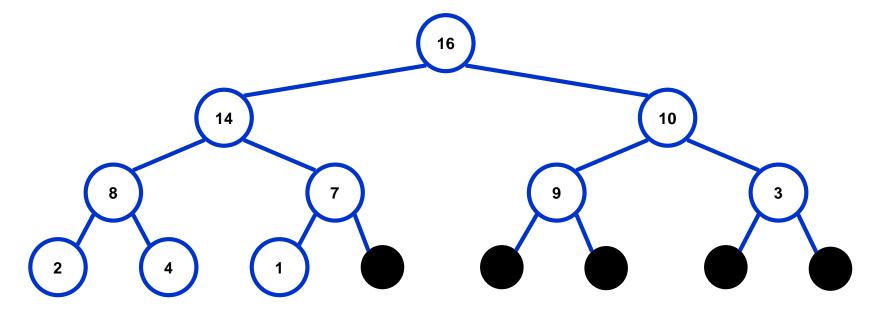

Heap sort

• A *heap* can be seen as a complete binary tree:

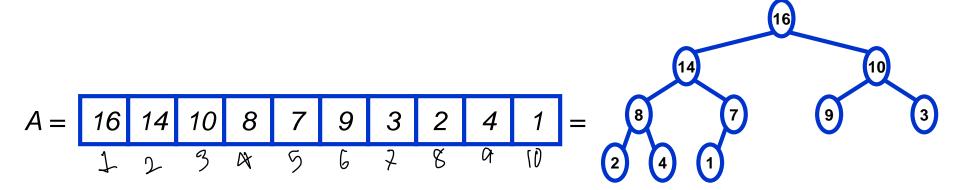

- What makes a binary tree complete?
- *Is the example above complete?*

• A *heap* can be seen as a complete binary tree:

■ The book calls them "nearly complete" binary trees; can think of unfilled slots as null pointers

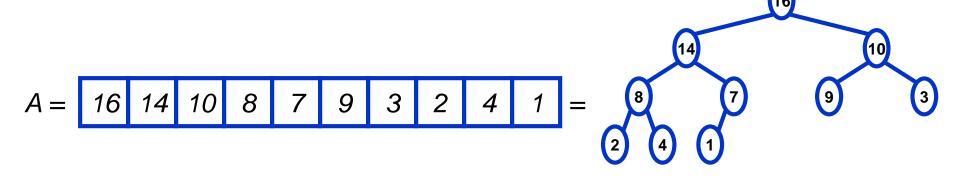

• In practice, heaps are usually implemented as arrays:

- To represent a complete binary tree as an array:
 - The root node is A[1]
 - Node i is A[i]

- The parent of node i is A[i/2] (note: integer divide)
- The left child of node i is A[2i]
- The right child of node i is A[2i + 1]

Referencing Heap Elements

• So...

```
Parent(i) { return [i/2]; }
Left(i) { return 2*i; }
right(i) { return 2*i + 1; }
```

- An aside: *How would you implement this most efficiently?*
- Another aside: *Really?*

The Heap Property

- which tes
- Heaps also satisfy the *heap property*:

 $A[Parent(i)] \ge A[i]$

for all nodes i > 1

- In other words, the value of a node is at most the value of its parent
- Where is the largest element in a heap stored?
- Definitions:
 - The *height* of a node in the tree = the number of edges on the longest downward path to a leaf
 - The height of a tree = the height of its root

Heap Height

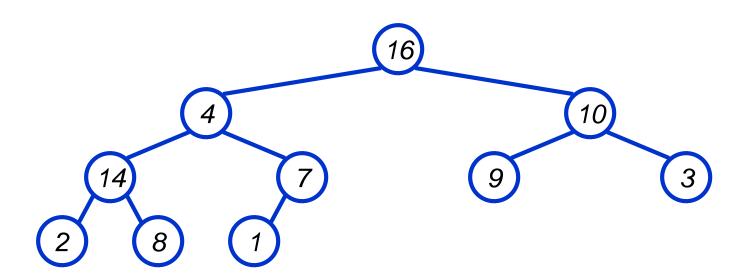

- \ 09N -
- What is the height of an n-element heap? Why?
- This is nice: basic heap operations take at most time proportional to the height of the heap

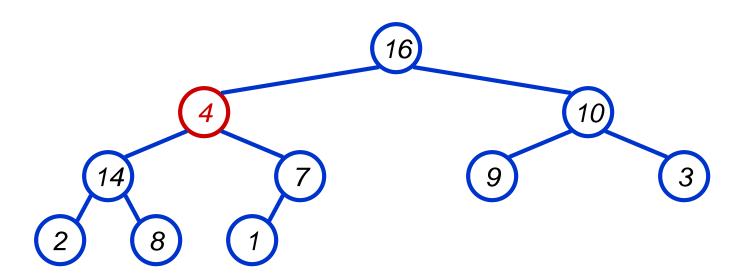

Heap Operations: Heapify()

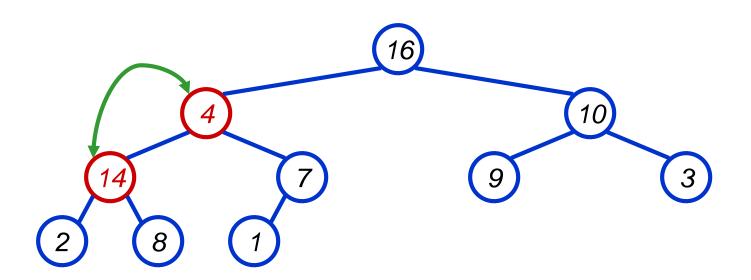

- **Heapify ()**: maintain the heap property
 - Given: a node i in the heap with children l and r
 - Given: two subtrees rooted at *l* and *r*, assumed to be heaps
 - Problem: The subtree rooted at *i* may violate the heap property (*How?*)
 - Action: let the value of the parent node "float down" so subtree at *i* satisfies the heap property
 - What do you suppose will be the basic operation between i, l, and r?

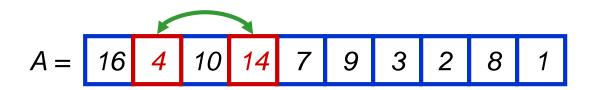

Heap Operations: Heapify()

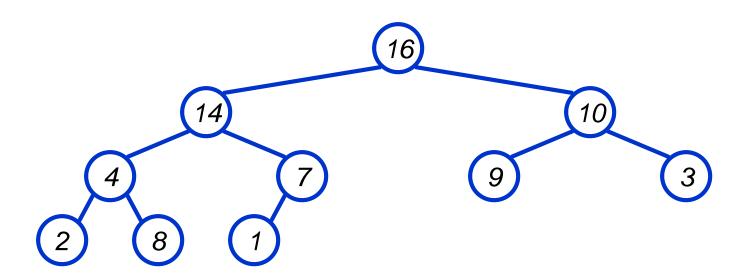

```
Heapify(A, i)
{
  l = Left(i); r = Right(i);
  if (1 \le \text{heap size}(A) \&\& A[1] > A[i])
      largest = 1;
  else
      largest = i;
  if (r <= heap_size(A) && A[r] > A[largest])
      largest = r;
  if (largest != i)
      Swap(A, i, largest);
      Heapify(A, largest);
```

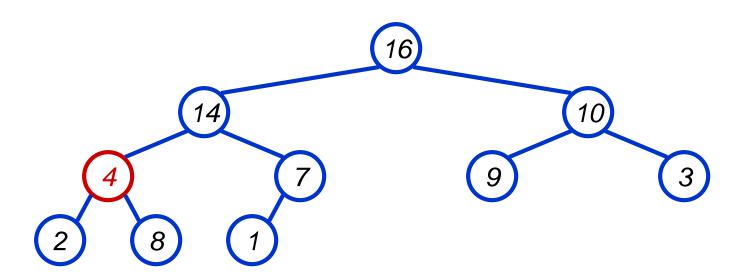

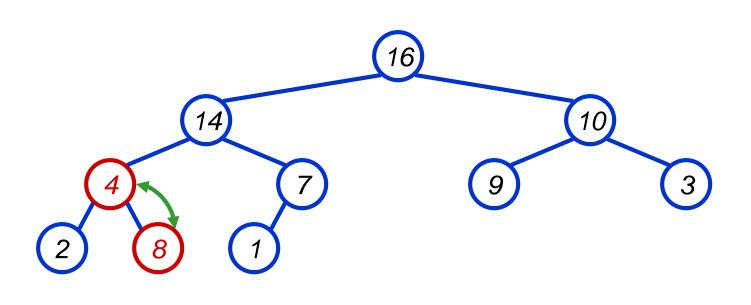

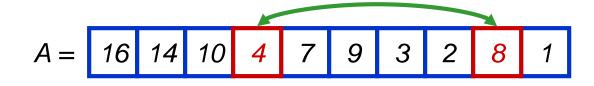

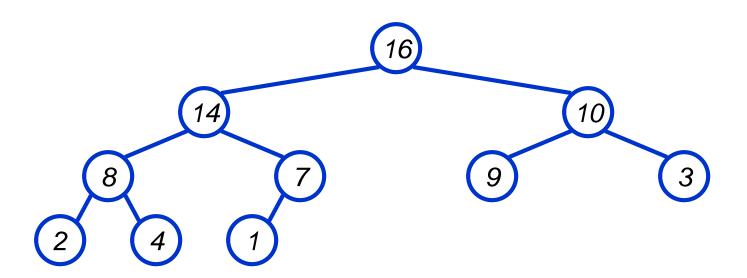

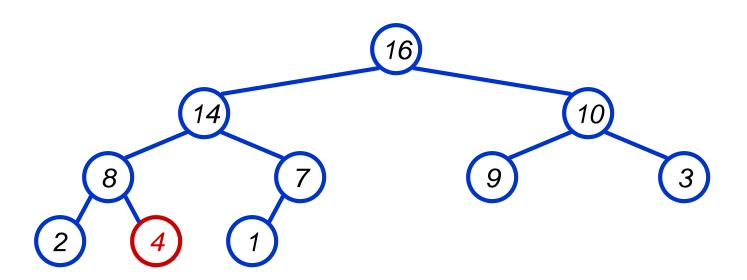

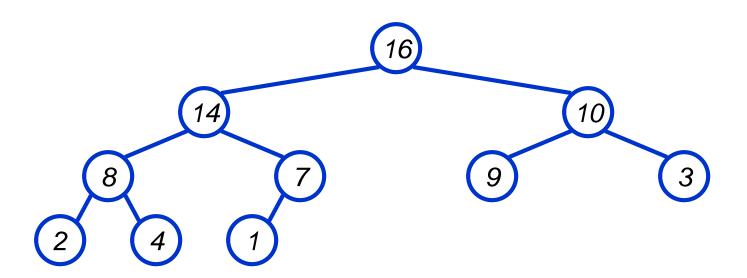

Analyzing Heapify(): Informal

- Aside from the recursive call, what is the running time of **Heapify()**?
- How many times can **Heapify()** recursively call itself?
- What is the worst-case running time of **Heapify()** on a heap of size n?

Analyzing Heapify(): Formal

- Fixing up relationships between i, l, and r takes $\Theta(1)$ time
- If the heap at i has n elements, how many elements can the subtrees at l or r have?
 - Draw it

 ∫ (N-1) is mal suitable
- Answer: 2n/3 (worst case: bottom row 1/2 full)
- So time taken by **Heapify()** is given by $T(n) \le T(2n/3) + \Theta(1)$

Analyzing Heapify(): Formal

So we have

$$T(n) \le T(2n/3) + \Theta(1)$$

- By case 2 of the Master Theorem, $T(n) = O(\lg n)$
- Thus, **Heapify()** takes linear time

Heap Operations: BuildHeap()

- We can build a heap in a bottom-up manner by running Heapify () on successive subarrays
 - Fact: for array of length *n*, all elements in range
 - - Walk backwards through the array from n/2 to 1, calling **Heapify()** on each node.
 - Order of processing guarantees that the children of node i are heaps when i is processed

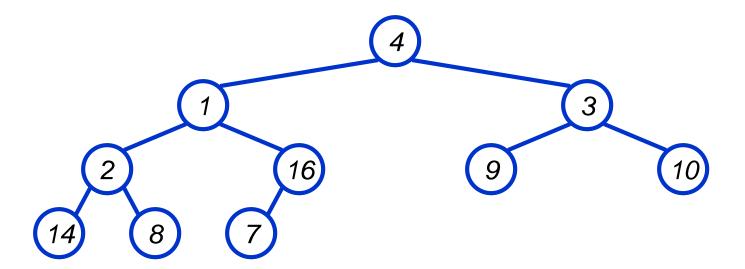

BuildHeap()

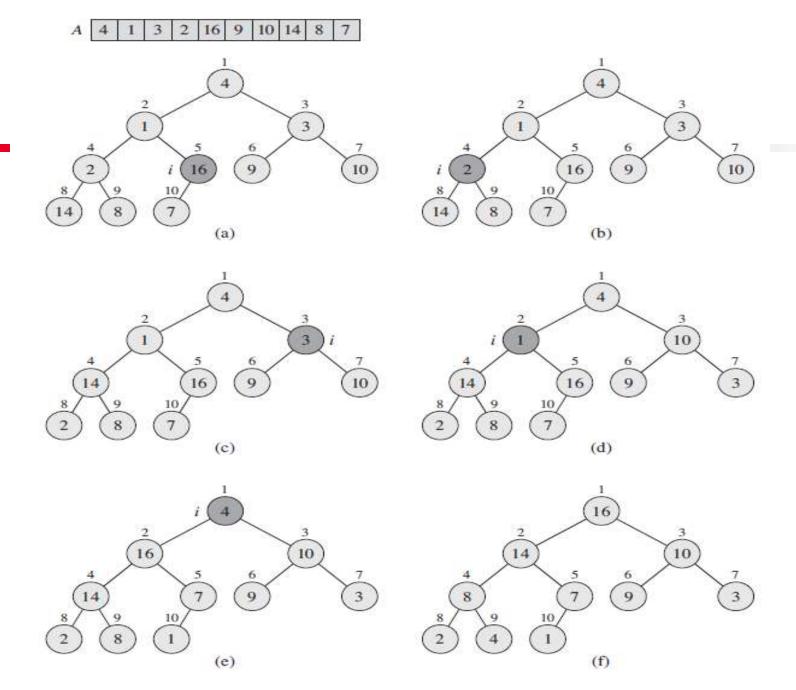

```
// given an unsorted array A, make A a heap
BuildHeap(A)
{
  heap_size(A) = length(A);
  for (i = \length[A]/2 \length downto 1)
        Heapify(A, i);
}
```

BuildHeap() Example

Work through example

$$A = \{4, 1, 3, 2, 16, 9, 10, 14, 8, 7\}$$

Analyzing BuildHeap()

- Each call to **Heapify()** takes $O(\lg n)$ time
- There are O(n) such calls (specifically, $\lfloor n/2 \rfloor$)
- Thus the running time is O(n lg n)
 Is this a correct asymptotic upper bound?

 - *Is this an asymptotically tight bound?*
- A tighter bound is O(n)
 - How can this be? Is there a flaw in the above reasoning?

Analyzing BuildHeap(): Tight

- To **Heapify()** a subtree takes O(h) time where h is the height of the subtree
 - $h = O(\lg m), m = \# \text{ nodes in subtree}$
 - The height of most subtrees is small
- Fact: an *n*-element heap has at most $\lceil n/2^{h+1} \rceil$ nodes of height h
- CLR 7.3 uses this fact to prove that BuildHeap () takes O(n) time

Heapsort

- Given BuildHeap(), an in-place sorting algorithm is easily constructed:
 - Maximum element is at A[1]
 - Discard by swapping with element at A[n]
 - Decrement heap_size[A]
 - A[n] now contains correct value
 - Restore heap property at A[1] by calling Heapify()
 - Repeat, always swapping A[1] for A[heap_size(A)]

Heapsort

```
2 ploming

Heapsort (A)
                                                                        BuildHeap (A);
                                                                             for (i = length(A) downto 2)
                                                                                                                                                            Swap(A[1], A[i]);
                                                                                                                                                         heap_size(A) -= 1;
Heapify(A, 1);
                                                                                                                                                                                                                      hence O(n/ogn)
```

Heapsort - Example

replace noot with highest index

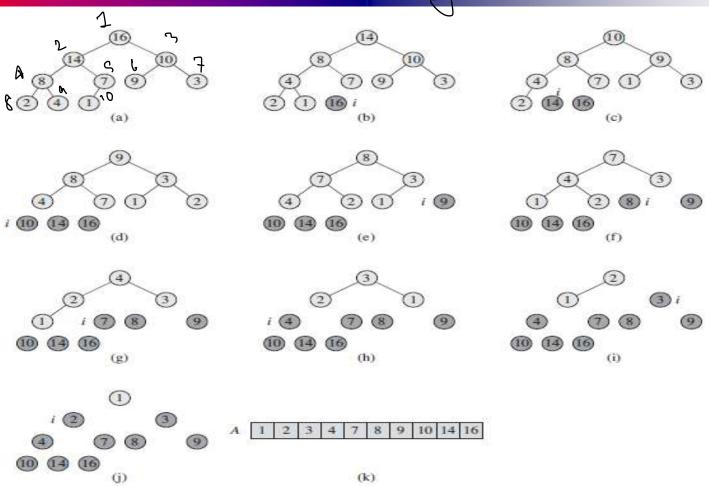

Figure 6.4 The operation of HEAPSORT. (a) The max-heap data structure just after BUILD-MAX-HEAP has built it in line 1. (b)-(j) The max-heap just after each call of MAX-HEAPIFY in line 5, showing the value of i at that time, Only lightly shaded nodes remain in the heap. (k) The resulting sorted array A.

Analyzing Heapsort

- The call to BuildHeap () takes O(n) time
- Each of the n 1 calls to **Heapify()** takes $O(\lg n)$ time
- Thus the total time taken by **HeapSort()**

```
= O(n) + (n - 1) O(\lg n)
```

$$= O(n) + O(n \lg n)$$

$$= O(n \lg n)$$

Priority Queues

- Heapsort is a nice algorithm, but in practice Quicksort usually wins
- But the heap data structure is incredibly useful for implementing *priority queues*
 - A data structure for maintaining a set *S* of elements, each with an associated value or *key*
 - Supports the operations Insert(), Maximum(), and ExtractMax()
 - What might a priority queue be useful for?

Priority Queue Operations

- Insert(S, x) inserts the element x into set S
- Maximum(S) returns the element of S with the maximum key
- ExtractMax(S) removes and returns the element of S with the maximum key
- How could we implement these operations using a heap?
 - *E.g.* scheduling jobs on a shared computer

Priority Queue Operations – Implementation of Extract-Max

```
HEAP-EXTRACT-MAX(A)
  if A.heap-size < 1
      error "heap underflow"
  max = A[1]
 A[1] = A[A.heap-size]
  A.heap-size = A.heap-size - 1
 MAX-HEAPIFY(A, 1)
   return max
```

EXTRACT-MAX(S) removes and returns the element of S with the largest key.
